

Factorising odd numbers

Any odd integer, m , greater than 1, can be factorised by expressing it as the difference of two squares, since if $m = x^2 - y^2$ then $m = (x+y)(x-y)$, so m has factors $x+y$ and $x-y$.

For example, $15 = 4^2 - 1^2 = (4+1)(4-1) = 5*3$.

Rearranging the first equation above gives $m + y^2 = x^2$, so we can find x and y by evaluating $m + y^2$ for $y = 0, 1, 2, \dots$ until the perfect square x^2 is found.

Write a program to factorise an odd integer greater than 1 by expressing it as the difference of two squares.

Input

The first line of the input is the number of cases (a positive integer, n , on one line).

This is followed by n odd integers greater than 1, each on a line of its own.

Output

The output should consist of:

$$m = x^2 - y^2 = (x+y)(x-y)$$

(with the actual values for m , x , and y).

Example

Input:

```
2
15
9929
```

Output:

```
15 = 4^2 - 1^2 = 5*3
9929 = 4965^2 - 4964^2 = 9929*1
```
